MRI THORACIC SPINE 28/10/2019 Reference: 6922322

MRI THORACIC SPINE

HISTORY:

Thoracic pain for over a month, radiating around the right thorax. Bone scan showed pathology at T8. CT showed old fracture T12. To define problem with MRI.

FINDINGS:

In keeping with the clinical history, there is a chronic wedge fracture of T12 with approximately 60% loss of anterior vertebral body height.

Furthermore, in keeping with the nuclear medicine bone scan, there are degenerative changes throughout the thoracic spine. The changes are worse at the facet articulations and based on today's MRI, the most severe facet changes are present bilaterally at T10/11, slightly worse on the right. This facet arthrosis results in osteophytes encroaching on the foramen.

No paravertebral mass, canal stenosis or abnormal signal within the cord.

COMMENT:

Noting the patient's right sided thoracic symptoms, there is a severe facet arthrosis on the right at T10/11 with osteophytes encroaching on the foramen. This could potentially be contributing to symptoms but please correlate carefully with the dermatome.
