General Report (1171254)		
Patient Name	DOB	URNO
Mrs Baptista, Eliane	14/05/1978	223865
Hip Right US (Jul 30 2025, 15:40); Hip Right Xray (Jul 30 2025, 15:49); Hip Left Xray (Jul 30 2025, 15:49)		

X-RAY PELVIS/BOTH HIPS AND ULTRASOUND RIGHT HIP

CLINICAL HISTORY:

18 months ongoing pain right greater than left hip, history of osteoarthritis, history of hypermobility and perimenopause suspecting difference in hip joints/asymmetry. Suspected trochanteric bursitis, failed physiotherapy, for injection if positive please.

FINDINGS:

X-RAY PELVIS/BOTH HIPS

There is slight elevation of the right acetabular roof compared to the left side, suggestive of minor dysplastic changes. The right central edge angle measures 29.2 degrees and the left central edge angle measures 34.5 degrees. No significant degenerative changes are noted at both hip joints. Both hip joints are well aligned. There are no radiographic signs to suggest sacroiliitis. No focal aggressive osseous lesion is noted at the pelvic bones.

ULTRASOUND RIGHT HIP

No anterior hip joint effusion is identified at the right hip. The iliopsoas tendon and rectus femoris insertion are normal in appearances. Similarly the tensor fascia lata and iliotibial band show no abnormality. There is no tear of the gluteus minimus and medius tendon. There is thickening of the greater trochanteric bursa.

COMMENT:

Mild right greater trochanteric bursitis is demonstrated.

Thank you for your referral.

Yours sincerely,

Dr Ashish Chawla

MBBS FRANZCR

Sonographer: A.L.
