Iron Studies

The normal ferritin implies normal iron stores. However, a normal ferritin level may be seen in iron deficient patients who have recently taken oral iron, or who have an intercurrent illness causing ferritin elevation.

HepBsAg	Negative	Negative	Negative	Negative		
HepBsAb		Trace				
HepBsAb		7				
HepC-IgG	Negative	Negative	Negative	Negative		

Comments on Collection 02-May-25 1523:

Hepatitis C IgG may not appear for up to six (6) months after primary infection.

If this is acute phase serum, suggest repeat at a suitable interval.

No evidence of active Hepatitis B infection. If this is an acute sample then retesting in 60-90 days (range 45-180 days) post exposure is indicated.

For further information on serological events in acute (self-limiting)

Hepatitis B infection see

HIV Ag/Ab	Negative	Negative	Negative	Negative	

Comments on Collection 02-May-25 1523:
HIV-1/HIV-2 antigen/antibody assay performed by Abbott CMIA.

Approximately 50-90% of patients report signs and symptoms suggestive of primary HIV infection at the time of seroconversion, which mostly occurs at 10-14 days after exposure (range 3 days to 10 weeks). Onset of symptoms often coincides with the detection of HIV antigen/antibodies although testing can be negative for up to 3 weeks after symptoms develop. Negative results performed less than 12 weeks after exposure should be repeated at least 12 weeks after exposure to exclude transmission.

Syphilis Antibody Negative Negative Negative Negative

Comments on Collection 02-May-25 1523:
 No treponemal antibodies detected.
 The Syphilis TP Chemiluminescent Microparticle Immunoassay (CMIA) is a screening test for T.pallidum antibodies.

This result may indicate:
 1. no exposure to T.pallidum.
 2. very early primary syphilis. If risk factors exist a further sample should be tested in 2-3 weeks. In symptomatic patients, a swab of mucocutaneous lesions for the detection of T.pallidum DNA by PCR may be positive before antibody production commences.

Repeat antenatal syphilis screening for high risk subjects should be considered at 28-32 weeks gestation and at delivery.

Rubella IgG	23	26	27	23		IU/mL

Comments on Collection 02-May-25 1523:
 Rubella IgG antibody detected suggesting past exposure or response to immunisation.
 This level of antibody is consistent with a protective level of immunity.

During pregnancy, if rubella contact has occurred, please notify the laboratory to arrange rubella IgM testing on the current sample and send a further serum 3-4 weeks after last contact or as soon as illness develops to exclude the low risk of rubella reinfection.

Rubella IgG Interpretation

Negative:	<5.0 IU/mL
Grayzone:	5.0-9.9 IU/mL
Low Positive:	10-20 IU/mL
Positive:	>20 IU/mL

VZV IgG	Positive	Positive	Positive			
VZVGI				2468.0		mIU/mL
VZIGG				Positive		

Comments on Collection 02-May-25 1523:
Immune status: Positive

Assay IgG Index Ranges:
Negative: <150 IU/mL
Positive: >=150 IU/mL

The uncertainty of measurement of this assay is +/-10% which equates to 135 to 165 at the cut-off of 150 IU/mL.

If clinical illness is suspected Varicella zoster is best diagnosed by swabbing the base of a lesion firmly for detection of VZV DNA by PCR.

VZV IgG testing is performed by CLIA.

hCG (Abbott)	17600	16	21	54	IU/L	

Comments on Collection 05-Mar-25 0826:

Pregnant - weeks after LMP	Reference Ranges
4	20 - 950
5	50 - 15000
6	200 - 150000
7 - 8	1200 - 250000
9 - 10	1400 - 170000
11 - 14	5000 - 140000
15 - 38	6000 - 75000
Non Pregnant	<2

Lower levels are seen in ectopic pregnancy and spontaneous abortion.
Increased levels may be seen with hydatidiform moles.
